1 Overview

Quagga is a routing software package that provides TCP/IP based routing services with routing protocols support such as RIPv1, RIPv2, RIPng, OSPFv2, OSPFv3, BGP-4, and BGP-4+ (see Section 1.4 [Supported RFC], page 3). Quagga also supports special BGP Route Reflector and Route Server behavior. In addition to traditional IPv4 routing protocols, Quagga also supports IPv6 routing protocols. With SNMP daemon which supports SMUX protocol, Quagga provides routing protocol MIBs (see Chapter 15 [SNMP Support], page 79).

Quagga uses an advanced software architecture to provide you with a high quality, multi server routing engine. Quagga has an interactive user interface for each routing protocol and supports common client commands. Due to this design, you can add new protocol daemons to Quagga easily. You can use Quagga library as your program's client user interface.

Zebra is distributed under the GNU General Public License.

1.1 About Quagga

Today, TCP/IP networks are covering all of the world. The Internet has been deployed in many countries, companies, and to the home. When you connect to the Internet your packet will pass many routers which have TCP/IP routing functionality.

A system with Quagga installed acts as a dedicated router. With Quagga, your machine exchanges routing information with other routers using routing protocols. Quagga uses this information to update the kernel routing table so that the right data goes to the right place. You can dynamically change the configuration and you may view routing table information from the Quagga terminal interface.

Adding to routing protocol support, Quagga can setup interface's flags, interface's address, static routes and so on. If you have a small network, or a stub network, or xDSL connection, configuring the Quagga routing software is very easy. The only thing you have to do is to set up the interfaces and put a few commands about static routes and/or default routes. If the network is rather large, or if the network structure changes frequently, you will want to take advantage of Quagga's dynamic routing protocol support for protocols such as RIP, OSPF or BGP. Quagga is with you.

Traditionally, UNIX based router configuration is done by ifconfig and route commands. Status of routing table is displayed by netstat utility. Almost of these commands work only if the user has root privileges. Quagga has a different system administration method. There are two user modes in Quagga. One is normal mode, the other is enable mode. Normal mode user can only view system status, enable mode user can change system configuration. This UNIX account independent feature will be great help to the router administrator.

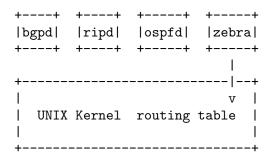

Currently, Quagga supports common unicast routing protocols. Multicast routing protocols such as BGMP, PIM-SM, PIM-DM may be supported in Quagga 2.0. MPLS support is going on. In the future, TCP/IP filtering control, QoS control, diffserv configuration will be added to Quagga. Quagga project's final goal is making a productive, quality free TCP/IP routing software.

1.2 System Architecture

Traditional routing software is made as a one process program which provides all of the routing protocol functionalities. Quagga takes a different approach. It is made from a collection of several daemons that work together to build the routing table. There may be several protocol-specific routing daemons and zebra the kernel routing manager.

The ripd daemon handles the RIP protocol, while ospfd is a daemon which supports OSPF version 2. bgpd supports the BGP-4 protocol. For changing the kernel routing table and for redistribution of routes between different routing protocols, there is a kernel routing table manager zebra daemon. It is easy to add a new routing protocol daemons to the entire routing system without affecting any other software. You need to run only the protocol daemon associated with routing protocols in use. Thus, user may run a specific daemon and send routing reports to a central routing console.

There is no need for these daemons to be running on the same machine. You can even run several same protocol daemons on the same machine. This architecture creates new possibilities for the routing system.

Quagga System Architecture

Multi-process architecture brings extensibility, modularity and maintainability. At the same time it also brings many configuration files and terminal interfaces. Each daemon has it's own configuration file and terminal interface. When you configure a static route, it must be done in zebra configuration file. When you configure BGP network it must be done in bgpd configuration file. This can be a very annoying thing. To resolve the problem, Quagga provides integrated user interface shell called vtysh. vtysh connects to each daemon with UNIX domain socket and then works as a proxy for user input.

Quagga was planned to use multi-threaded mechanism when it runs with a kernel that supports multi-threads. But at the moment, the thread library which comes with GNU/Linux or FreeBSD has some problems with running reliable services such as routing software, so we don't use threads at all. Instead we use the select(2) system call for multiplexing the events.

When zebra runs under a GNU Hurd kernel it will act as a kernel routing table itself. Under GNU Hurd, all TCP/IP services are provided by user processes called pfinet. Quagga will provide all the routing selection mechanisms for the process. This feature will be implemented when GNU Hurd becomes stable.

1.3 Supported Platforms

Currently Quagga supports GNU/Linux, BSD and Solaris. Below is a list of OS versions on which Quagga runs. Porting Quagga to other platforms is not so too difficult. Platform dependent codes exist only in zebra daemon. Protocol daemons are platform independent. Please let us know when you find out Quagga runs on a platform which is not listed below.

- GNU/Linux 2.0.37
- GNU/Linux 2.2.x and higher
- FreeBSD 2.2.8
- FreeBSD 3.x
- FreeBSD 4.x
- NetBSD 1.4
- OpenBSD 2.5
- Solaris 2.6
- Solaris 7

Some IPv6 stacks are in development. Quagga supports following IPv6 stacks. For BSD, we recommend KAME IPv6 stack. Solaris IPv6 stack is not yet supported.

- Linux IPv6 stack for GNU/Linux 2.2.x and higher.
- KAME IPv6 stack for BSD.
- INRIA IPv6 stack for BSD.

1.4 Supported RFC

Below is the list of currently supported RFC's.

- RFC1058 Routing Information Protocol. C.L. Hedrick. Jun-01-1988.
- RF2082 RIP-2 MD5 Authentication. F. Baker, R. Atkinson. January 1997.
- RFC2453 RIP Version 2. G. Malkin. November 1998.
- RFC2080 RIPng for IPv6. G. Malkin, R. Minnear. January 1997.
- RFC2328 OSPF Version 2. J. Moy. April 1998.
- RFC2370 The OSPF Opaque LSA Option R. Coltun. July 1998.
- RFC3101 The OSPF Not-So-Stubby Area (NSSA) Option P. Murphy. January 2003.
- RFC2740 OSPF for IPv6. R. Coltun, D. Ferguson, J. Moy. December 1999.
- RFC1771 A Border Gateway Protocol 4 (BGP-4). Y. Rekhter & T. Li. March 1995.
- RFC1965 Autonomous System Confederations for BGP. P. Traina. June 1996.
- RFC1997 BGP Communities Attribute. R. Chandra, P. Traina & T. Li. August 1996.
- RFC2545 Use of BGP-4 Multiprotocol Extensions for IPv6 Inter-Domain Routing. P. Marques, F. Dupont. March 1999.

RFC2796 BGP Route Reflection An alternative to full mesh IBGP. T. Bates & R. Chandrasekeran. June 1996.

RFC2858 Multiprotocol Extensions for BGP-4. T. Bates, Y. Rekhter, R. Chandra, D. Katz. June 2000.

RFC2842 Capabilities Advertisement with BGP-4. R. Chandra, J. Scudder. May 2000. When SNMP support is enabled, below RFC is also supported.

RFC1227 SNMP MUX protocol and MIB. M.T. Rose. May-01-1991.

RFC1657 Definitions of Managed Objects for the Fourth Version of the Border Gateway Protocol (BGP-4) using SMIv2. S. Willis, J. Burruss, J. Chu, Editor. July 1994.

RFC1724 RIP Version 2 MIB Extension. G. Malkin & F. Baker. November 1994.

RFC1850 OSPF Version 2 Management Information Base. F. Baker, R. Coltun. November 1995.

1.5 How to get Quagga

Quagga is still beta software and there is no officially released version. Once Quagga is released you can get it from GNU FTP site and its mirror sites. We are planning Quagga-1.0 as the first released version.

Zebra's official web page is located at:

http://www.gnu.org/software/zebra/zebra.html.

The original Zebra web site is located at:

http://www.zebra.org/.

As of this writing, development by zebra.org on Zebra has slowed down. Some work is being done by third-parties to try maintain bug-fixes and enhancements to the current Zebra code-base, which has resulted in a fork of Zebra called Quagga, see:

http://www.quagga.net/.

for further information, as well as links to additional zebra resources.

1.6 Mailing List

There is a mailing list for discussions about Quagga. If you have any comments or suggestions to Quagga, please subscribe to http://lists.quagga.net/mailman/listinfo/quagga-users.

There is an additional mailing list, ZNOG (znog@dishone.st) for general discussion of zebra related issues and network operation. To subscribe send an email to znog-subscribe@dishone.st with a message body that includes only:

subscribe znog

To unsubscribe, send an email to znog-unsubscribe@dishone.st with a message body that includes only:

unsubscribe znog

Alternatively, you may use the web interface located at http://www.dishone.st/mailman/listinfo/zr Links to archives of the znog list are available at this URL.

1.7 Bug Reports

If you think you have found a bug, please send a bug report to http://bugzilla.quagga.net.

When you send a bug report, please be careful about the points below.

- Please note what kind of OS you are using. If you use the IPv6 stack please note that as well.
- Please show us the results of netstat -rn and ifconfig -a. Information from zebra's VTY command show ip route will also be helpful.
- Please send your configuration file with the report. If you specify arguments to the configure script please note that too.

Bug reports are very important for us to improve the quality of Quagga. Quagga is still in the development stage, but please don't hesitate to send a bug report to http://bugzilla.quagga.net.

2 Installation

There are three steps for installing the software: configuration, compilation, and installation.

The easiest way to get Quagga running is to issue the following commands:

- % configure
- % make
- % make install

2.1 Configure the Software

Quagga has an excellent configure script which automatically detects most host configurations. There are several additional configure options you can use to turn off IPv6 support, to disable the compilation of specific daemons, and to enable SNMP support.

'--enable-guile'

Turn on compilation of the zebra-guile interpreter. You will need the guile library to make this. zebra-guile implementation is not yet finished. So this option is only useful for zebra-guile developers.

'--disable-ipv6'

Turn off IPv6 related features and daemons. Quagga configure script automatically detects IPv6 stack. But sometimes you might want to disable IPv6 support of Quagga.

'--disable-zebra'

Do not build zebra daemon.

'--disable-ripd'

Do not build ripd.

'--disable-ripngd'

Do not build ripngd.

'--disable-ospfd'

Do not build ospfd.

'--disable-ospf6d'

Do not build ospf6d.

'--disable-bgpd'

Do not build bgpd.

'--disable-bgp-announce'

Make bgpd which does not make bgp announcements at all. This feature is good for using bgpd as a BGP announcement listener.

'--enable-netlink'

Force to enable GNU/Linux netlink interface. Quagga configure script detects netlink interface by checking a header file. When the header file does not match to the current running kernel, configure script will not turn on netlink support.

'--enable-snmp'

Enable SNMP support. By default, SNMP support is disabled.

'--enable-nssa'

Enable support for Not So Stubby Area (see RC3101) in ospfd.

'--enable-opaque-lsa'

Enable support for Opaque LSAs (RFC2370) in ospfd.

'--disable-ospfapi'

Disable support for OSPF-API, an API to interface directly with ospfd. OSPF-API is enabled if –enable-opaque-lsa is set.

'--disable-ospfclient'

Disable building of the example OSPF-API client.

'--enable-ospf-te'

Enable support for OSPF Traffic Engineering Extension (internet-draft) this requires support for Opaque LSAs.

$\verb|`--enable-multipath=| ARG| \\$

Enable support for Equal Cost Multipath. ARG is the maximum number of ECMP paths to allow, set to 0 to allow unlimited number of paths.

'--enable-rtady'

Enable support IPV6 router advertisement in zebra.

You may specify any combination of the above options to the configure script. By default, the executables are placed in '/usr/local/sbin' and the configuration files in '/usr/local/etc'. The '/usr/local/' installation prefix and other directories may be changed using the following options to the configuration script.

'--prefix=prefix'

Install architecture-independent files in *prefix* [/usr/local].

'--sysconfdir=dir'

Look for configuration files in dir [prefix/etc]. Note that sample configuration files will be installed here.

`--localstatedir=dir"

Configure zebra to use dir for local state files, such as pid files and unix sockets.

Additionally, you may configure zebra to drop its elevated privileges shortly after startup and switch to another user, there are three configure options to control zebra's behaviour.

'--enable-user=user'

Switch to user ARG shortly after startup, and run as user ARG in normal operation.

'--enable-group=group'

Switch real and effective group to group shortly after startup.

'--enable-vty-group=group'

Create Unix Vty sockets (for use with vtysh) with group owndership set to group. This allows one to create a seperate group which is restricted to accessing

only the Vty sockets, hence allowing one to delegate this group to individual users, or to run vtysh setgid to this group.

The default user and group which will be configured is 'quagga' if no user or group is specified. Note that this user or group requires write access to the local state directory (see –localstatedir) and requires at least read access, and write access if you wish to allow daemons to write out their configuration, to the configuration directory (see –sysconfdir).

On systems which have the 'libcap' capabilities manipulation library (currently only linux), the quagga system will retain only minimal capabilities required, further it will only raise these capabilities for brief periods. On systems without libcap, quagga will run as the user specified and only raise its uid back to uid 0 for brief periods.

% ./configure --disable-ipv6

This command will configure zebra and the routing daemons.

There are several options available only to GNU/Linux systems:¹.

CONFIG_NETLINK

Kernel/User netlink socket. This is a brand new feature which enables an advanced interface between the Linux kernel and zebra (see Chapter 14 [Kernel Interface], page 77).

CONFIG_RTNETLINK

Routing messages. This makes it possible to receive netlink routing messages. If you specify this option, zebra can detect routing information updates directly from the kernel (see Chapter 14 [Kernel Interface], page 77).

$CONFIG_IP_MULTICAST$

IP: multicasting. This option should be specified when you use ripd or ospfd because these protocols use multicast.

IPv6 support has been added in GNU/Linux kernel version 2.2. If you try to use the Quagga IPv6 feature on a GNU/Linux kernel, please make sure the following libraries have been installed. Please note that these libraries will not be needed when you uses GNU C library 2.1 or upper.

inet6-apps

The inet6-apps package includes basic IPv6 related libraries such as inet_ntop and inet_pton. Some basic IPv6 programs such as ping, ftp, and inetd are also included. The inet-apps can be found at ftp://ftp.inner.net/pub/ipv6/.

net-tools

The net-tools package provides an IPv6 enabled interface and routing utility. It contains ifconfig, route, netstat, and other tools. net-tools may be found at http://www.tazenda.demon.co.uk/phil/net-tools/.

¹ GNU/Linux has very flexible kernel configuration features. If you use GNU/Linux, make sure that the current kernel configuration is what you want. Quagga will run with any kernel configuration but some recommendations do exist.

2.2 Build the Software

After configuring the software, you will need to compile it for your system. Simply issue the command make in the root of the source directory and the software will be compiled. If you have *any* problems at this stage, be certain to send a bug report See Section 1.7 [Bug Reports], page 5.

```
% ./configure
.
.
.
./configure output
.
.
.
.
```

2.3 Install the Software

Installing the software to your system consists of copying the compiled programs and supporting files to a standard location. After the installation process has completed, these files have been copied from your work directory to '/usr/local/bin', and '/usr/local/etc'.

To install the Quagga suite, issue the following command at your shell prompt: make install.

```
% % make install %
```

Quagga daemons have their own terminal interface or VTY. After installation, you have to setup each beast's port number to connect to them. Please add the following entries to '/etc/services'.

```
zebrasrv
               2600/tcp
                          # zebra service
               2601/tcp
                          # zebra vtv
zebra
               2602/tcp
                          # RIPd vty
ripd
ripngd
               2603/tcp
                          # RIPngd vty
ospfd
               2604/tcp
                          # OSPFd vty
               2605/tcp
bgpd
                          # BGPd vty
               2606/tcp
ospf6d
                          # OSPF6d vty
ospfapi
               2607/tcp
                          # ospfapi
isisd
               2608/tcp
                          # ISISd vty
```

If you use a FreeBSD newer than 2.2.8, the above entries are already added to '/etc/services' so there is no need to add it. If you specify a port number when starting the daemon, these entries may not be needed.

You may need to make changes to the config files in '/usr/local/etc/*.conf'. See Section 3.1 [Config Commands], page 11.

3 Basic commands

There are five routing daemons in use, and there is one manager daemon. These daemons may be located on separate machines from the manager daemon. Each of these daemons will listen on a particular port for incoming VTY connections. The routing daemons are:

- ripd, ripngd, ospfd, ospf6d, bgpd
- zebra

The following sections discuss commands common to all the routing daemons.

3.1 Config Commands

In a config file, you can write the debugging options, a vty's password, routing daemon configurations, a log file name, and so forth. This information forms the initial command set for a routing beast as it is starting.

Config files are generally found in:

'/usr/local/etc/*.conf'

Each of the daemons has its own config file. For example, zebra's default config file name is:

'/usr/local/etc/zebra.conf'

The daemon name plus '.conf' is the default config file name. You can specify a config file using the -f or --config-file options when starting the daemon.

3.1.1 Basic Config Commands

hostname hostname

Command

Set hostname of the router.

password password

Command

Set password for vty interface. If there is no password, a vty won't accept connections.

enable password password

Command

Set enable password.

log stdout no log stdout

Command Command

Set logging output to stdout.

log file filename

Command

If you want to log into a file please specify filename as follows.

log file /usr/local/etc/bgpd.log

log syslog no log syslog Command

Command

Set logging output to syslog.

write terminal Command

Displays the current configuration to the vty interface.

write file Command

Write current configuration to configuration file.

configure terminal

Command

Change to configuration mode. This command is the first step to configuration.

terminal length <0-512>

Command

Set terminal display length to <0-512>. If length is 0, no display control is performed.

who

list

List commands.

service password-encryption

Command

Encrypt password.

service advanced-vty

Command

Enable advanced mode VTY.

service terminal-length <0-512>

Command

Set system wide line configuration. This configuration command applies to all VTY interfaces.

show version Command

Show the current version of the Quagga and its build host information.

line vty

Command

Enter vty configuration mode.

banner motd default

Command

Set default motd string.

no banner motd Command

No motd banner string will be printed.

exec-timeout minute

Line Command

exec-timeout minute second

Line Command

Set VTY connection timeout value. When only one argument is specified it is used for timeout value in minutes. Optional second argument is used for timeout value in seconds. Default timeout value is 10 minutes. When timeout value is zero, it means no timeout.

no exec-timeout Line Command

Do not perform timeout at all. This command is as same as exec-timeout 0 0.

access-class access-list

Line Command

Restrict vty connections with an access list.

3.1.2 Sample Config File

Below is a sample configuration file for the zebra daemon.

```
! Zebra configuration file ! hostname Router password zebra enable password zebra ! log stdout !
```

'!' and '#' are comment characters. If the first character of the word is one of the comment characters then from the rest of the line forward will be ignored as a comment.

password zebra!password

If a comment character is not the first character of the word, it's a normal character. So in the above example '!' will not be regarded as a comment and the password is set to 'zebra!password'.

3.2 Common Invocation Options

These options apply to all Quagga daemons.

```
'-d'
'--daemon'
Runs in daemon mode.

'-f file'
'--config_file=file'
Set configuration file name.
'-h'
'--help' Display this help and exit.
'-i file'
'--pid_file=file'
```

Upon startup the process identifier of the daemon is written to a file, typically in '/var/run'. This file can be used by the init system to implement commands such as .../init.d/zebra status, .../init.d/zebra restart or .../init.d/zebra stop.

The file name is an run-time option rather than a configure-time option so that multiple routing daemons can be run simultaneously. This is useful when using

Quagga to implement a routing looking glass. One machine can be used to collect differing routing views from differing points in the network.

3.3 Virtual Terminal Interfaces

Print program version.

 ${
m VTY-Virtual\ Terminal\ [aka\ TeletYpe]}$ Interface is a command line interface (CLI) for user interaction with the routing daemon.

3.3.1 VTY Overview

VTY stands for Virtual TeletYpe interface. It means you can connect to the daemon via the telnet protocol.

To enable a VTY interface, you have to setup a VTY password. If there is no VTY password, one cannot connect to the VTY interface at all.

```
% telnet localhost 2601
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
Hello, this is zebra (version 0.96)
Copyright 1997-2000 Kunihiro Ishiguro
```

User Access Verification

```
Password: XXXXX
Router> ?
 enable
                    Turn on privileged commands
                    Exit current mode and down to previous mode
 exit
                    Description of the interactive help system
 help
 list
                    Print command list
                    Show running system information
 show
 who
                    Display who is on a vty
Router> enable
Password: XXXXX
Router# configure terminal
Router(config)# interface eth0
Router(config-if)# ip address 10.0.0.1/8
Router(config-if)# ^Z
Router#
```

3.3.2 VTY Modes

There are three basic VTY modes:

There are commands that may be restricted to specific VTY modes.

3.3.2.1 VTY View Mode

This mode is for read-only access to the CLI. One may exit the mode by leaving the system, or by entering enable mode.

3.3.2.2 VTY Enable Mode

This mode is for read-write access to the CLI. One may exit the mode by leaving the system, or by escaping to view mode.

3.3.2.3 VTY Other Modes

This page is for describing other modes.

^{&#}x27;?' is very useful for looking up commands.

3.3.3 VTY CLI Commands

Commands that you may use at the command-line are described in the following three subsubsections.

3.3.3.1 CLI Movement Commands

These commands are used for moving the CLI cursor. The \bigcirc character means press the Control Key.

C-f

 $\langle \overline{RIGHT} \rangle$ Move forward one character.

C-b

 $\langle \overline{\text{LEFT}} \rangle$ Move backward one character.

M-f Move forward one word.

M-b Move backward one word.

C-a Move to the beginning of the line.

C-e Move to the end of the line.

3.3.3.2 CLI Editing Commands

These commands are used for editing text on a line. The $\langle \mathbb{C} \rangle$ character means press the Control Key.

C-h

(DEL) Delete the character before point.

C-d Delete the character after point.

M-d Forward kill word.

C-w Backward kill word.

C-k Kill to the end of the line.

C-u Kill line from the beginning, erasing input.

C-t Transpose character.

3.3.3.3 CLI Advanced Commands

There are several additional CLI commands for command line completions, insta-help, and VTY session management.

C-c Interrupt current input and moves to the next line.

C-z End current configuration session and move to top node.

C-n

(DOWN) Move down to next line in the history buffer.

C-p

(UP) Move up to previous line in the history buffer.

TAB Use command line completion by typing (TAB).

You can use command line help by typing help at the beginning of the line. Typing? at any point in the line will show possible completions.

Chapter 4: Zebra

4 Zebra

zebra is an IP routing manager. It provides kernel routing table updates, interface lookups, and redistribution of routes between different routing protocols.

4.1 Invoking zebra

Besides the common invocation options (see Section 3.2 [Common Invocation Options], page 13), the zebra specific invocation options are listed below.

'-b'

'--batch' Runs in batch mode. zebra parses configuration file and terminates immediately.

'-k'

'--keep_kernel'

When zebra starts up, don't delete old self inserted routes.

·-1 '

'--log_mode'

Set verbose logging on.

'-r'

'--retain'

When program terminates, retain routes added by zebra.

4.2 Interface Commands

interface ifname Command

shutdownInterface Commandno shutdownInterface Command

Up or down the current interface.

ip addressaddress/prefixInterface Commandip6 addressaddress/prefixInterface Commandno ip addressaddress/prefixInterface Commandno ip6 addressaddress/prefixInterface Command

Set the IPv4 or IPv6 address/prefix for the interface.

ip address address/prefix secondary no ip address address/prefix secondary Interface Command
Interface Command

Set the secondary flag for this address. This causes ospfd to not treat the address as a distinct subnet.

description description ...

Interface Command

Set description for the interface.

multicastInterface Commandno multicastInterface Command

Enable or disables multicast flag for the interface.

bandwidth <1-10000000> no bandwidth <1-10000000>

Interface Command Interface Command

Set bandwidth value of the interface in kilobits/sec. This is for calculating OSPF cost. This command does not affect the actual device configuration.

link-detect no link-detect

Interface Command
Interface Command

Enable/disable link-detect on platforms which support this. Currently only linux and with certain drivers - those which properly support the IFF_RUNNING flag.

4.3 Static Route Commands

Static routing is a very fundamental feature of routing technology. It defines static prefix and gateway.

ip route network gateway

Command

network is destination prefix with format of A.B.C.D/M. gateway is gateway for the prefix. When gateway is A.B.C.D format. It is taken as a IPv4 address gateway. Otherwise it is treated as an interface name. If the interface name is null0 then zebra installs a blackhole route.

```
ip route 10.0.0.0/8 10.0.0.2
ip route 10.0.0.0/8 ppp0
ip route 10.0.0.0/8 null0
```

First example defines 10.0.0.0/8 static route with gateway 10.0.0.2. Second one defines the same prefix but with gateway to interface ppp0. The third install a blackhole route.

ip route network netmask gateway

Command

This is alternate version of above command. When *network* is A.B.C.D format, user must define *netmask* value with A.B.C.D format. *gateway* is same option as above command

```
ip route 10.0.0.0 255.255.255.0 10.0.0.2
ip route 10.0.0.0 255.255.255.0 ppp0
ip route 10.0.0.0 255.255.255.0 null0
```

These statements are equivalent to those in the previous example.

ip route network gateway distance

Command

Installs the route with the specified distance.

Multiple nexthop static route

Chapter 4: Zebra 21

```
ip route 10.0.0.1/32 10.0.0.2 ip route 10.0.0.1/32 10.0.0.3 ip route 10.0.0.1/32 eth0
```

If there is no route to 10.0.0.2 and 10.0.0.3, and interface eth0 is reachable, then the last route is installed into the kernel.

If zebra has been compiled with multipath support, and both 10.0.0.2 and 10.0.0.3 are reachable, zebra will install a multipath route via both nexthops, if the platform supports this.

This will install a multihop route via the specified next-hops if they are reachable, as well as a high-metric blackhole route, which can be useful to prevent traffic destined for a prefix to match less-specific routes (eg default) should the specified gateways not be reachable. Eg:

```
zebra> show ip route 10.0.0.0/8
Routing entry for 10.0.0.0/8
  Known via "static", distance 1, metric 0
    10.0.0.2 inactive
    10.0.0.3 inactive

Routing entry for 10.0.0.0/8
  Known via "static", distance 255, metric 0
    directly connected, Null0
```

```
ipv6 route network gateway
ipv6 route network gateway distance
```

Command

Command

These behave similarly to their ipv4 counterparts.

table tableno Command

Select the primary kernel routing table to be used. This only works for kernels supporting multiple routing tables (like GNU/Linux 2.2.x and later). After setting tableno with this command, static routes defined after this are added to the specified table.

4.4 zebra Terminal Mode Commands

show ip route Command

Display current routes which zebra holds in its database.

```
Router# show ip route
```

Codes: K - kernel route, C - connected, S - static, R - RIP, B - BGP * - FIB route.

K* 0.0.0.0/0 203.181.89.241 S 0.0.0.0/0 203.181.89.1

C* 127.0.0.0/8 lo C* 203.181.89.240/28 eth0

show ipv6 route

Command

show interface Command

show ipforward

Command

Display whether the host's IP forwarding function is enabled or not. Almost any UNIX kernel can be configured with IP forwarding disabled. If so, the box can't work as a router.

show ipv6forward

Command

Display whether the host's IP v6 forwarding is enabled or not.

Chapter 5: RIP

5 RIP

RIP – Routing Information Protocol is widely deployed interior gateway protocol. RIP was developed in the 1970s at Xerox Labs as part of the XNS routing protocol. RIP is a distance-vector protocol and is based on the Bellman-Ford algorithms. As a distance-vector protocol, RIP router send updates to its neighbors periodically, thus allowing the convergence to a known topology. In each update, the distance to any given network will be broadcasted to its neighboring router.

ripd supports RIP version 2 as described in RFC2453 and RIP version 1 as described in RFC1058.

5.1 Starting and Stopping ripd

The default configuration file name of ripd's is 'ripd.conf'. When invocation ripd searches directory /usr/local/etc. If 'ripd.conf' is not there next search current directory.

RIP uses UDP port 520 to send and receive RIP packets. So the user must have the capability to bind the port, generally this means that the user must have superuser privileges. RIP protocol requires interface information maintained by zebra daemon. So running zebra is mandatory to run ripd. Thus minimum sequence for running RIP is like below:

```
# zebra -d
# ripd -d
```

Please note that zebra must be invoked before ripd.

To stop ripd. Please use kill 'cat /var/run/ripd.pid'. Certain signals have special meaningss to ripd.

'SIGHUP' Reload configuration file 'ripd.conf'. All configurations are reseted. All routes learned so far are cleared and removed from routing table.

'SIGUSR1' Rotate ripd logfile.

'SIGINT'

'SIGTERM' ripd sweeps all installed RIP routes then terminates properly.

ripd invocation options. Common options that can be specified (see Section 3.2 [Common Invocation Options], page 13).

```
'-r'
'--retain'
```

When the program terminates, retain routes added by ripd.

5.1.1 RIP netmask

The netmask features of ripd support both version 1 and version 2 of RIP. Version 1 of RIP originally contained no netmask information. In RIP version 1, network classes were originally used to determine the size of the netmask. Class A networks use 8 bits of mask, Class B networks use 16 bits of masks, while Class C networks use 24 bits of mask. Today, the most widely used method of a network mask is assigned to the packet on the basis of the interface that received the packet. Version 2 of RIP supports a variable length subnet mask (VLSM). By extending the subnet mask, the mask can be divided and reused. Each

subnet can be used for different purposes such as large to middle size LANs and WAN links. Quagga ripd does not support the non-sequential netmasks that are included in RIP Version 2.

In a case of similar information with the same prefix and metric, the old information will be suppressed. Ripd does not currently support equal cost multipath routing.

5.2 RIP Configuration

router rip Command

The router rip command is necessary to enable RIP. To disable RIP, use the no router rip command. RIP must be enabled before carrying out any of the RIP commands.

no router rip Command

Disable RIP.

RIP can be configured to process either Version 1 or Version 2 packets, the default mode is Version 2. If no version is specified, then the RIP daemon will default to Version 2. If RIP is set to Version 1, the setting "Version 1" will be displayed, but the setting "Version 2" will not be displayed whether or not Version 2 is set explicitly as the version of RIP being used. The version can be specified globally, and also on a per-interface basis (see below).

version version RIP Command

Set RIP process's version. version can be '1" or '2".

network network

RIP Command

no network network

RIP Command

Set the RIP enable interface by *network*. The interfaces which have addresses matching with *network* are enabled.

This group of commands either enables or disables RIP interfaces between certain numbers of a specified network address. For example, if the network for 10.0.0.0/24 is RIP enabled, this would result in all the addresses from 10.0.0.0 to 10.0.0.255 being enabled for RIP. The no network command will disable RIP for the specified network.

network ifname

RIP Command

no network ifname

RIP Command

Set a RIP enabled interface by *ifname*. Both the sending and receiving of RIP packets will be enabled on the port specified in the network ifname command. The no network ifname command will disable RIP on the specified interface.

neighbor a.b.c.d

RIP Command

no neighbor a.b.c.d

RIP Command

Specify RIP neighbor. When a neighbor doesn't understand multicast, this command is used to specify neighbors. In some cases, not all routers will be able to understand multicasting, where packets are sent to a network or a group of addresses. In a situation where a neighbor cannot process multicast packets, it is necessary to establish a

Chapter 5: RIP

direct link between routers. The neighbor command allows the network administrator to specify a router as a RIP neighbor. The no neighbor a.b.c.d command will disable the RIP neighbor.

Below is very simple RIP configuration. Interface eth0 and interface which address match to 10.0.0.0/8 are RIP enabled.

```
!
router rip
network 10.0.0.0/8
network eth0
!
```

Passive interface

passive-interface (IFNAME | default) no passive-interface IFNAME

RIP command

RIP command

This command sets the specified interface to passive mode. On passive mode interface, all receiving packets are processed as normal and ripd does not send either multicast or unicast RIP packets except to RIP neighbors specified with neighbor command. The interface may be specified as default to make ripd default to passive on all interfaces.

The default is to be passive on all interfaces.

RIP version handling

ip rip send version version

Interface command

version can be '1', '2', '1 2'. This configuration command overrides the router's rip version setting. The command will enable the selected interface to send packets with RIP Version 1, RIP Version 2, or both. In the case of '1 2', packets will be both broadcast and multicast.

The default is to send only version 2.

ip rip receive version version

Interface command

Version setting for incoming RIP packets. This command will enable the selected interface to receive packets in RIP Version 1, RIP Version 2, or both.

The default is to receive both versions.

RIP split-horizon

ip split-horizon no ip split-horizon

Interface command Interface command

Control split-horizon on the interface. Default is ip split-horizon. If you don't perform split-horizon on the interface, please specify no ip split-horizon.

5.3 How to Announce RIP route

| redistribute kernel | RIP command |
|---|-------------|
| redistribute kernel metric <0-16> | RIP command |
| redistribute kernel route-map route-map | RIP command |
| no redistribute kernel | RIP command |

redistribute kernel redistributes routing information from kernel route entries into the RIP tables. no redistribute kernel disables the routes.

| redistribute static | RIP command |
|---|-------------|
| redistribute static metric <0-16> | RIP command |
| redistribute static route-map route-map | RIP command |
| no redistribute static | RIP command |

redistribute static redistributes routing information from static route entries into the RIP tables. no redistribute static disables the routes.

| redistribute connected | RIP command |
|--|-------------|
| redistribute connected metric <0-16> | RIP command |
| redistribute connected route-map route-map | RIP command |
| no redistribute connected | RIP command |

Redistribute connected routes into the RIP tables. no redistribute connected disables the connected routes in the RIP tables. This command redistribute connected of the interface which RIP disabled. The connected route on RIP enabled interface is announced by default.

| redistribute ospf | RIP command |
|---------------------------------------|-------------|
| redistribute ospf metric <0-16> | RIP command |
| redistribute ospf route-map route-map | RIP command |
| no redistribute ospf | RIP command |

redistribute ospf redistributes routing information from ospf route entries into the RIP tables. no redistribute ospf disables the routes.

| redistribute bgp | RIP command |
|--------------------------------------|-------------|
| redistribute bgp metric <0-16> | RIP command |
| redistribute bgp route-map route-map | RIP command |
| no redistribute bgp | RIP command |

redistribute bgp redistributes routing information from bgp route entries into the RIP tables. no redistribute bgp disables the routes.

If you want to specify RIP only static routes:

default-information originate

RIP command

route a.b.c.d/mRIP commandno route a.b.c.d/mRIP command

This command is specific to Quagga. The route command makes a static route only inside RIP. This command should be used only by advanced users who are particularly

Chapter 5: RIP 27

knowledgeable about the RIP protocol. In most cases, we recommend creating a static route in Quagga and redistributing it in RIP using redistribute static.

5.4 Filtering RIP Routes

RIP routes can be filtered by a distribute-list.

distribute-list access_list direct ifname

Command

You can apply access lists to the interface with a distribute-list command. access_list is the access list name. direct is 'in' or 'out'. If direct is 'in' the access list is applied to input packets.

The distribute-list command can be used to filter the RIP path. distribute-list can apply access-lists to a chosen interface. First, one should specify the access-list. Next, the name of the access-list is used in the distribute-list command. For example, in the following configuration 'eth0' will permit only the paths that match the route 10.0.0.0/8

```
!
router rip
  distribute-list private in eth0
!
access-list private permit 10 10.0.0.0/8
access-list private deny any
!
```

distribute-list can be applied to both incoming and outgoing data.

distribute-list prefix prefix_list (in|out) ifname

Command

You can apply prefix lists to the interface with a distribute-list command. pre-fix_list is the prefix list name. Next is the direction of 'in' or 'out'. If direct is 'in' the access list is applied to input packets.

5.5 RIP Metric Manipulation

RIP metric is a value for distance for the network. Usually ripd increment the metric when the network information is received. Redistributed routes' metric is set to 1.

default-metric <1-16> no default-metric <1-16>

RIP command

RIP command

This command modifies the default metric value for redistributed routes. The default value is 1. This command does not affect connected route even if it is redistributed by redistribute connected. To modify connected route's metric value, please use redistribute connected metric or route-map. offset-list also affects connected routes.

```
offset-list access-list (in|out)
offset-list access-list (in|out) ifname
```

RIP command

RIP command

5.6 RIP distance

Distance value is used in zebra daemon. Default RIP distance is 120.

distance <1-255> no distance <1-255>

RIP command

RIP command

Set default RIP distance to specified value.

distance <1-255> *A.B.C.D/M* no distance <1-255> *A.B.C.D/M* RIP command

RIP command

Set default RIP distance to specified value when the route's source IP address matches the specified prefix.

distance <1-255> A.B.C.D/M access-list no distance <1-255> A.B.C.D/M access-list RIP command

Set default RIP distance to specified value when the route's source IP address matches the specified prefix and the specified access-list.

5.7 RIP route-map

Usage of ripd's route-map support.

Optional argument route-map MAP_NAME can be added to each ${\tt redistribute}$ statement.

```
redistribute static [route-map MAP_NAME]
redistribute connected [route-map MAP_NAME]
```

Cisco applies route-map _before_ routes will exported to rip route table. In current Quagga's test implementation, ripd applies route-map after routes are listed in the route table and before routes will be announced to an interface (something like output filter). I think it is not so clear, but it is draft and it may be changed at future.

Route-map statement (see Chapter 12 [Route Map], page 73) is needed to use route-map functionality.

match interface word

Route Map

This command match to incoming interface. Notation of this match is different from Cisco. Cisco uses a list of interfaces - NAME1 NAME2 ... NAMEN. Ripd allows only one name (maybe will change in the future). Next - Cisco means interface which includes next-hop of routes (it is somewhat similar to "ip next-hop" statement). Ripd means interface where this route will be sent. This difference is because "next-hop" of same routes which sends to different interfaces must be different. Maybe it'd be better to made new matches - say "match interface-out NAME" or something like that.

match ip address word match ip address prefix-list word Route Map

Match if route destination is permitted by access-list.

Chapter 5: RIP

match ip next-hop A.B.C.D

Route Map

Cisco uses here <access-list>, ripd IPv4 address. Match if route has this next-hop (meaning next-hop listed in the rip route table - "show ip rip")

match metric <0-4294967295>

Route Map

This command match to the metric value of RIP updates. For other protocol compatibility metric range is shown as <0-4294967295>. But for RIP protocol only the value range <0-16> make sense.

set ip next-hop A.B.C.D

Route Map

This command set next hop value in RIPv2 protocol. This command does not affect RIPv1 because there is no next hop field in the packet.

set metric <0-4294967295>

Route Map

Set a metric for matched route when sending announcement. The metric value range is very large for compatibility with other protocols. For RIP, valid metric values are from 1 to 16.

5.8 RIP Authentication

ip rip authentication mode md5 no ip rip authentication mode md5

Interface command

Interface command

Set the interface with RIPv2 MD5 authentication.

ip rip authentication mode text no ip rip authentication mode text

Interface command
Interface command

Set the interface with RIPv2 simple password authentication.

ip rip authentication string string no ip rip authentication string string

Interface command

Interface command

RIP version 2 has simple text authentication. This command sets authentication string. The string must be shorter than 16 characters.

ip rip authentication key-chain key-chain no ip rip authentication key-chain key-chain

Interface command
Interface command

Specifiy Keyed MD5 chain.

```
!
key chain test
key 1
  key-string test
!
interface eth1
  ip rip authentication mode md5
  ip rip authentication key-chain test
```

5.9 RIP Timers

timers basic update timeout garbage

RIP command

RIP protocol has several timers. User can configure those timers' values by timers basic command.

The default settings for the timers are as follows:

- The update timer is 30 seconds. Every update timer seconds, the RIP process is awakened to send an unsolicited Response message containing the complete routing table to all neighboring RIP routers.
- The timeout timer is 180 seconds. Upon expiration of the timeout, the route is no longer valid; however, it is retained in the routing table for a short time so that neighbors can be notified that the route has been dropped.
- The garbage collect timer is 120 seconds. Upon expiration of the garbage-collection timer, the route is finally removed from the routing table.

The timers basic command allows the default values of the timers listed above to be changed.

no timers basic

RIP command

The no timers basic command will reset the timers to the default settings listed above.

5.10 Show RIP Information

To display RIP routes.

show ip rip

Command

Show RIP routes.

The command displays all RIP routes. For routes that are received through RIP, this command will display the time the packet was sent and the tag information. This command will also display this information for routes redistributed into RIP.

show ip protocols

Command

The command displays current RIP status. It includes RIP timer, filtering, version, RIP enabled interface and RIP peer inforation.

Chapter 5: RIP

```
ripd> show ip protocols
Routing Protocol is "rip"
  Sending updates every 30 seconds with +/-50%, next due in 35 seconds
 Timeout after 180 seconds, garbage collect after 120 seconds
  Outgoing update filter list for all interface is not set
  Incoming update filter list for all interface is not set
 Default redistribution metric is 1
 Redistributing: kernel connected
 Default version control: send version 2, receive version 2
    Interface
                     Send Recv
 Routing for Networks:
    eth0
    eth1
    1.1.1.1
    203.181.89.241
 Routing Information Sources:
    Gateway
                     BadPackets BadRoutes Distance Last Update
```

5.11 RIP Debug Commands

Debug for RIP protocol.

debug rip events

Command

Debug rip events.

debug rip will show RIP events. Sending and receiving packets, timers, and changes in interfaces are events shown with ripd.

debug rip packet

Command

Debug rip packet.

debug rip packet will display detailed information about the RIP packets. The origin and port number of the packet as well as a packet dump is shown.

debug rip zebra

Command

Debug rip between zebra communication.

This command will show the communication between ripd and zebra. The main information will include addition and deletion of paths to the kernel and the sending and receiving of interface information.

show debugging rip

Command

Display ripd's debugging option.

show debugging rip will show all information currently set for ripd debug.

Chapter 6: RIPng 33

6 RIPng

ripngd supports the RIPng protocol as described in RFC2080. It's an IPv6 reincarnation of the RIP protocol.

6.1 Invoking ripngd

There are no ripngd specific invocation options. Common options can be specified (see Section 3.2 [Common Invocation Options], page 13).

6.2 ripngd Configuration

Currently ripngd supports the following commands:

router ripng Command

Enable RIPng.

flush_timer time RIPng Command

Set flush timer.

network network RIPng Command

Set RIPng enabled interface by network

network ifname RIPng Command

Set RIPng enabled interface by ifname

route network RIPng Command

Set RIPng static routing announcement of network.

router zebra Command

This command is the default and does not appear in the configuration. With this statement, RIPng routes go to the zebra daemon.

6.3 ripngd Terminal Mode Commands

show ip ripng Command

show debugging ripng Command

debug ripng events Command

debug ripng packet Command

debug ripng zebra Command

6.4 ripngd Filtering Commands

distribute-list access_list (in | out) ifname

Command

You can apply an access-list to the interface using the distribute-list command. access_list is an access-list name. direct is 'in' or 'out'. If direct is 'in', the access-list is applied only to incoming packets.

distribute-list local-only out sit1

7 OSPFv2

OSPF version 2 is a routing protocol which described in RFC2328 - OSPF Version 2. OSPF is IGP (Interior Gateway Protocols). Compared with RIP, OSPF can provide scalable network support and faster convergence time. OSPF is widely used in large networks such as ISP backbone and enterprise networks.

7.1 Configuring ospfd

There is no ospfd specific options. Common options can be specified (see Section 3.2 [Common Invocation Options], page 13) to ospfd needs interface information from zebra. So please make it sure zebra is running before invoking ospfd.

Like other daemons, ospfd configuration is done in OSPF specific configuration file 'ospfd.conf'.

7.2 OSPF router

To start OSPF process you have to specify the OSPF router. As of this writing, ospfd does not support multiple OSPF processes.

router ospf
no router ospf
Command

Enable or disable the OSPF process. ospfd does not yet support multiple OSPF processes. So you can not specify an OSPF process number.

ospf router-id a.b.c.d no ospf router-id

OSPF Command
OSPF Command

ospf abr-type type no ospf abr-type type OSPF Command
OSPF Command

type can be cisco|ibm|shortcut|standard More information regarding the behaviour controlled by this command can be found in draft-ietf-ospf-abr-alt-05.txt and draft-ietf-ospf-shortcut-abr-02.txt Quote: "Though the definition of the Area Border Router (ABR) in the OSPF specification does not require a router with multiple attached areas to have a backbone connection, it is actually necessary to provide successful routing to the inter-area and external destinations. If this requirement is not met, all traffic destined for the areas not connected to such an ABR or out of the OSPF domain, is dropped. This document describes alternative ABR behaviors implemented in Cisco and IBM routers."

ospf rfc1583compatibility no ospf rfc1583compatibility

OSPF Command
OSPF Command

This rfc2328, the sucessor to rfc1583, suggests according to section G.2 (changes) in section 16.4 a change to the path preference algorithm that prevents possible routing loops that were possible in the old version of OSPFv2. More specifically it demands that inter-area paths and intra-area path are now of equal preference but still both preferred to external paths.

| OSPF Command OSPF Command |
|--|
| OSPF Command OSPF Command |
| OSPF Command OSPF Command OSPF Command |
| OSPF Command OSPF Command |
| OSPF Command OSPF Command OSPF Command |
| |

This command specifies the OSPF enabled interface(s). If the interface has an address from range 192.168.1.0/24 then the command below enables ospf on this interface so router can provide network information to the other ospf routers via this interface.

```
router ospf
network 192.168.1.0/24 area 0.0.0.0
```

Prefix length in interface must be equal or bigger (ie. smaller network) than prefix length in network statement. For example statement above doesn't enable ospf on interface with address 192.168.1.1/23, but it does on interface with address 192.168.1.129/25.

7.3 OSPF area

```
area a.b.c.d range a.b.c.d/mOSPF Commandarea <0-4294967295> range a.b.c.d/mOSPF Commandno area a.b.c.d range a.b.c.d/mOSPF Commandno area <0-4294967295> range a.b.c.d/mOSPF Command
```

Summarize intra area paths from specified area into one Type-3 summary-LSA announced to other areas. This command can be used only in ABR and ONLY router-LSAs (Type-1) and network-LSAs (Type-2) (ie. LSAs with scope area) can be summarized. Type-5 AS-external-LSAs can't be summarized - their scope is AS. Summarizing Type-7 AS-external-LSAs isn't supported yet by Quagga.

```
router ospf
network 192.168.1.0/24 area 0.0.0.0
network 10.0.0.0/8 area 0.0.0.10
area 0.0.0.10 range 10.0.0.0/8
```

With configuration above one Type-3 Summary-LSA with routing info 10.0.0.0/8 is announced into backbone area if area 0.0.0.10 contains at least one intra-area network (ie. described with router or network LSA) from this range.

area a.b.c.d range IPV4_PREFIX not-advertise no area a.b.c.d range IPV4_PREFIX not-advertise

OSPF Command

OSPF Command Instead of summarizing intra area paths filter them - ie. intra area paths from this range are not advertised into other areas. This command makes sense in ABR only.

area a.b.c.d range IPV4_PREFIX substitute IPV4_PREFIX

OSPF Command

no area a.b.c.d range IPV4_PREFIX substitute IPV4_PREFIX

OSPF Command

Substitute summarized prefix with another prefix.

router ospf

network 192.168.1.0/24 area 0.0.0.0 network 10.0.0.0/8 area 0.0.0.10

area 0.0.0.10 range 10.0.0.0/8 substitute 11.0.0.0/8

One Type-3 summary-LSA with routing info 11.0.0.0/8 is announced into backbone area if area 0.0.0.10 contains at least one intra-area network (ie. described with router-LSA or network-LSA) from range 10.0.0.0/8. This command makes sense in ABR only.

| area a.b.c.d virtual-link a.b.c.d area <0-4294967295> virtual-link a.b.c.d no area a.b.c.d virtual-link a.b.c.d no area <0-4294967295> virtual-link a.b.c.d | OSPF Command OSPF Command OSPF Command |
|--|--|
| area a.b.c.d shortcut area <0-4294967295> shortcut no area a.b.c.d shortcut no area <0-4294967295> shortcut | OSPF Command OSPF Command OSPF Command |
| area a.b.c.d stub area <0-4294967295> stub no area a.b.c.d stub no area <0-4294967295> stub | OSPF Command OSPF Command OSPF Command |
| area a.b.c.d stub no-summary area <0-4294967295> stub no-summary no area a.b.c.d stub no-summary no area <0-4294967295> stub no-summary | OSPF Command OSPF Command OSPF Command |
| area a.b.c.d default-cost <0-16777215> no area a.b.c.d default-cost <0-16777215> | OSPF Command |
| area a.b.c.d export-list NAME area <0-4294967295> export-list NAME no area a.b.c.d export-list NAME no area <0-4294967295> export-list NAME | OSPF Command OSPF Command OSPF Command |

Filter Type-3 summary-LSAs announced to other areas originated from intra- area paths from specified area.

```
router ospf
network 192.168.1.0/24 area 0.0.0.0
network 10.0.0.0/8 area 0.0.0.10
area 0.0.0.10 export-list foo
!
access-list foo permit 10.10.0.0/16
access-list foo deny any
```

With example above any intra-area paths from area 0.0.0.10 and from range 10.10.0.0/16 (for example 10.10.1.0/24 and 10.10.2.128/30) are announced into other areas as Type-3 summary-LSA's, but any others (for example 10.11.0.0/16 or 10.128.30.16/30) aren't. This command makes sense in ABR only.

| area a.b.c.d import-list NAME | OSPF Command |
|---|--------------|
| area <0-4294967295> import-list NAME | OSPF Command |
| no area a.b.c.d import-list NAME | OSPF Command |
| no area <0-4294967295> import-list NAME | OSPF Command |

Same as export-list, but it applies to paths announced into specified area as Type-3 summary-LSAs.

| area a.b.c.d filter-list prefix NAME in | OSPF Command |
|--|--------------|
| area a.b.c.d filter-list prefix NAME out | OSPF Command |
| area <0-4294967295> filter-list prefix NAME in | OSPF Command |
| area <0-4294967295> filter-list prefix NAME out | OSPF Command |
| no area a.b.c.d filter-list prefix NAME in | OSPF Command |
| no area a.b.c.d filter-list prefix NAME out | OSPF Command |
| no area <0-4294967295> filter-list prefix NAME in | OSPF Command |
| no area <0-4294967295> filter-list prefix NAME out | OSPF Command |

Filtering Type-3 summary-LSAs to/from area using prefix lists. This command makes sense in ABR only.

| area a.b.c.d authentication | OSPF Command |
|---------------------------------------|--------------|
| area <0-4294967295> authentication | OSPF Command |
| no area a.b.c.d authentication | OSPF Command |
| no area <0-4294967295> authentication | OSPF Command |

| area a.b.c.d authentication message-digest | OSPF Command |
|---|--------------|
| area <0-4294967295> authentication message-digest | OSPF Command |

7.4 OSPF interface

ip ospf authentication-key AUTH_KEY no ip ospf authentication-key

Interface Command
Interface Command

Set OSPF authentication key to a simple password. After setting AUTH_KEY, all OSPF packets are authenticated. AUTH_KEY has length up to 8 chars.

ip ospf message-digest-key KEYID md5 KEY no ip ospf message-digest-key

Interface Command
Interface Command

Set OSPF authentication key to a cryptographic password. The cryptographic algorithm is MD5. KEYID identifies secret key used to create the message digest. KEY is the actual message digest key up to 16 chars. Note that OSPF MD5 authentication requires that time never go backwards, even across resets, if ospfd is to be able to promptly reestabish adjacencies with it's neighbours after restarts/reboots. The host should have system time be set at boot from an external source (eg battery backed clock, NTP, etc.) if MD5 authentication is to be expected to work reliably.

ip ospf cost <1-65535> no ip ospf cost

Interface Command
Interface Command

Set link cost for the specified interface. The cost value is set to router-LSA's metric field and used for SPF calculation.

ip ospf dead-interval <1-65535> no ip ospf dead-interval

Interface Command

Interface Command

Set number of seconds for RouterDeadInterval timer value used for Wait Timer and Inactivity Timer. This value must be the same for all routers attached to a common network. The default value is 40 seconds.

ip ospf hello-interval <1-65535> no ip ospf hello-interval

Interface Command

Interface Command

Set number of seconds for HelloInterval timer value. Setting this value, Hello packet will be sent every timer value seconds on the specified interface. This value must be the same for all routers attached to a common network. The default value is 10 seconds.

ip ospf network

Interface Command

$\begin{array}{ccc} & \text{(broadcast | non-broadcast | point-to-multipoint | point-to-point)} \\ \text{no ip ospf network} & \text{Interface Command} \end{array}$

Set explicitly network type for specifed interface.

ip ospf priority <0-255> no ip ospf priority

Interface Command

Interface Command

Set RouterPriority integer value. Setting higher value, router will be more eligible to become Designated Router. Setting the value to 0, router is no longer eligible to Designated Router. The default value is 1.

ip ospf retransmit-interval <1-65535> no ip ospf retransmit interval

Interface Command

Interface Command

Set number of seconds for RxmtInterval timer value. This value is used when retransmitting Database Description and Link State Request packets. The default value is 5 seconds.

ip ospf transmit-delay no ip ospf transmit-delay

Interface Command
Interface Command

Set number of seconds for InfTransDelay value. LSAs' age should be incremented by this value when transmitting. The default value is 1 seconds.

7.5 Redistribute routes to OSPF

| redistribute (kernel connected static rip bgp) | OSPF Command |

8 OSPFv3

ospf6d is a daemon support OSPF version 3 for IPv6 network. OSPF for IPv6 is described in RFC2740.

8.1 OSPF6 router

router ospf6 Command

router-id a.b.c.d OSPF6 Command

Set router's Router-ID.

interface ifname area area

OSPF6 Command

Bind interface to specified area, and start sending OSPF packets. area can be specified as 0.

8.2 OSPF6 area

Area support for OSPFv3 is not yet implemented.

8.3 OSPF6 interface

ipv6 ospf6 cost COST Interface Command

Sets interface's output cost. Default value is 1.

ipv6 ospf6 hello-interval HELLOINTERVAL Interface Command

Sets interface's Hello Interval. Default 40

ipv6 ospf6 dead-interval DEADINTERVAL Interface Command

Sets interface's Router Dead Interval. Default value is 40.

ipv6 ospf6 retransmit-interval Interface Command

RETRANSMITINTERVAL
Sets interface's Rxmt Interval. Default value is 5.

ipv6 ospf6 priority PRIORITY Interface Command

Sets interface's Router Priority. Default value is 1.

ipv6 ospf6 transmit-delay TRANSMITDELAY Interface Command

Sets interface's Inf-Trans-Delay. Default value is 1.

8.4 Redistribute routes to OSPF6

redistribute staticOSPF6 Commandredistribute connectedOSPF6 Commandredistribute ripngOSPF6 Command

8.5 Showing OSPF6 information

show ipv6 ospf6 [INSTANCE_ID]

Command

INSTANCE_ID is an optional OSPF instance ID. To see router ID and OSPF instance ID, simply type "show ipv6 ospf6 <cr>".

show ipv6 ospf6 database

Command

This command shows LSA database summary. You can specify the type of LSA.

show ipv6 ospf6 interface

Command

To see OSPF interface configuration like costs.

show ipv6 ospf6 neighbor

Command

Shows state and chosen (Backup) DR of neighbor.

show ipv6 ospf6 request-list A.B.C.D

Command

Shows requestlist of neighbor.

show ipv6 route ospf6

Command

This command shows internal routing table.

9 BGP

BGP stands for a Border Gateway Protocol. The lastest BGP version is 4. It is referred as BGP-4. BGP-4 is one of the Exterior Gateway Protocols and de-fact standard of Inter Domain routing protocol. BGP-4 is described in RFC1771 - A Border Gateway Protocol 4 (BGP-4).

Many extentions are added to RFC1771. RFC2858 - Multiprotocol Extensions for BGP-4 provide multiprotocol support to BGP-4.

9.1 Starting BGP

Default configuration file of bgpd is 'bgpd.conf'. bgpd searches the current directory first then /usr/local/etc/bgpd.conf. All of bgpd's command must be configured in 'bgpd.conf'.

bgpd specific invocation options are described below. Common options may also be specified (see Section 3.2 [Common Invocation Options], page 13).

```
'-p PORT'
'--bgp_port=PORT'
Set the bgp protocol's port number.
'-r'
'--retain'
```

When program terminates, retain BGP routes added by zebra.

9.2 BGP router

First of all you must configure BGP router with router bgp command. To configure BGP router, you need AS number. AS number is an identification of autonomous system. BGP protocol uses the AS number for detecting whether the BGP connection is internal one or external one.

router bgp asn Command

Enable a BGP protocol process with the specified asn. After this statement you can input any BGP Commands. You can not create different BGP process under different asn without specifying multiple-instance (see Section 9.13.1 [Multiple instance], page 61).

no router bgp asn

Command

Destroy a BGP protocol process with the specified asn.

bgp router-id A.B.C.D

BGP

This command specifies the router-ID. If bgpd connects to zebra it gets interface and address information. In that case default router ID value is selected as the largest IP Address of the interfaces. When router zebra is not enabled bgpd can't get interface information so router-id is set to 0.0.0.0. So please set router-id by hand.

9.2.1 BGP distance

distance bgp <1-255> <1-255> <1-255>

BGP

This command change distance value of BGP. Each argument is distance value for external routes, internal routes and local routes.

distance <**1-255>** *A.B.C.D/M* **distance** <**1-255>** *A.B.C.D/M word*

BGP BGP

This command set distance value to

9.2.2 BGP decision process

- 1. Weight check
- 2. Local preference check.
- 3. Local route check.
- 4. AS path length check.
- 5. Origin check.
- 6. MED check.

9.3 BGP network

9.3.1 BGP route

network A.B.C.D/M

BGP

This command adds the announcement network.

router bgp 1
network 10.0.0.0/8

This configuration example says that network 10.0.0.0/8 will be announced to all neighbors. Some vendors' routers don't advertise routes if they aren't present in their IGP routing tables; bgp doesn't care about IGP routes when announcing its routes.

no network A.B.C.D/M

BGP

9.3.2 Route Aggregation

aggregate-address A.B.C.D/M

BGP

This command specifies an aggregate address.

aggregate-address A.B.C.D/M as-set

BGP

This command specifies an aggregate address. Resulting routes inlucde AS set.

aggregate-address A.B.C.D/M summary-only

BGP

This command specifies an aggregate address. Aggreated routes will not be announce.

no aggregate-address A.B.C.D/M

BGP

9.3.3 Redistribute to BGP

redistribute kernel BGP

Redistribute kernel route to BGP process.

redistribute static BGP

Redistribute static route to BGP process.

redistribute connected BGP

Redistribute connected route to BGP process.

redistribute rip BGP

Redistribute RIP route to BGP process.

redistribute ospf BGP

Redistribute OSPF route to BGP process.

9.4 BGP Peer

9.4.1 Defining Peer

neighbor peer remote-as asn

BGP

Creates a new neighbor whose remote-as is as n. peer can be an IPv4 address or an IPv6 address.

```
router bgp 1
neighbor 10.0.0.1 remote-as 2
```

In this case my router, in AS-1, is trying to peer with AS-2 at 10.0.0.1.

This command must be the first command used when configuring a neighbor. If the remote-as is not specified, bgpd will complain like this:

can't find neighbor 10.0.0.1

9.4.2 BGP Peer commands

In a router bgp clause there are neighbor specific configurations required.

neighbor peer shutdown no neighbor peer shutdown

BGP BGP

BGP

BGP

Shutdown the peer. We can delete the neighbor's configuration by no neighbor peer remote-as as-number but all configuration of the neighbor will be deleted. When you want to preserve the configuration, but want to drop the BGP peer, use this syntax.

neighbor peer ebgp-multihop no neighbor peer ebgp-multihop

| neighbor peer description no neighbor peer description Set description of the peer. | BGP BGP |
|--|-------------------|
| neighbor peer version version Set up the neighbor's BGP version. version can be 4, 4+ or 4 BGP version 4 the default value used for BGP peering. BGP version 4+ means that the neighbor supports Multiprotocol Extensions for BGP-4. BGP version 4- is similar but to neighbor speaks the old Internet-Draft revision 00's Multiprotocol Extensions BGP-4. Some routing software is still using this version. | oor the |
| neighbor peer interface ifname no neighbor peer interface ifname When you connect to a BGP peer over an IPv6 link-local address, you have to spec the ifname of the interface used for the connection. | BGP BGP ify |
| neighbor peer next-hop-self no neighbor peer next-hop-self This command specifies an announced route's nexthop as being equivalent to taddress of the bgp router. | BGP BGP the |
| neighbor peer update-source no neighbor peer update-source | BGP BGP |
| neighbor peer default-originate no neighbor peer default-originate bgpd's default is to not announce the default route (0.0.0.0/0) even it is in routi table. When you want to announce default routes to the peer, use this command. | BGP BGP |
| neighbor peer port port neighbor peer port port | BGP BGP |
| neighbor peer send-community neighbor peer send-community | BGP BGP |
| neighbor peer weight weight no neighbor peer weight weight This command specifies a default weight value for the neighbor's routes. | BGP BGP |
| neighbor peer maximum-prefix number no neighbor peer maximum-prefix number | BGP BGP |

BGP

9.4.3 Peer filtering

neighbor peer distribute-list name [in|out]

BGP

This command specifies a distribute-list for the peer. direct is 'in' or 'out'.

neighbor peer prefix-list name [in|out]

BGP command

neighbor peer filter-list name [in|out]

BGP command

neighbor peer route-map name [in|out]

BGP

Apply a route-map on the neighbor. direct must be in or out.

9.5 BGP Peer Group

neighbor word peer-group

BGP

This command defines a new peer group.

neighbor peer peer-group word

BGP

This command bind specific peer to peer group word.

9.6 BGP Address Family

9.7 Autonomous System

AS (Autonomous System) is one of the essential element of BGP. BGP is a distance vector routing protocol. AS framework provides distance vector metric and loop detection to BGP. RFC1930 - Guidelines for creation, selection, and registration of an Autonomous System (AS) describes how to use AS.

AS number is tow octet digita value. So the value range is from 1 to 65535. AS numbers 64512 through 65535 are defined as private AS numbers. Private AS numbers must not to be advertised in the global Internet.

9.7.1 AS Path Regular Expression

AS path regular expression can be used for displaying BGP routes and AS path access list. AS path regular expression is based on POSIX 1003.2 regular expressions. Following description is just a subset of POSIX regular expression. User can use full POSIX regular expression. Adding to that special character '_' is added for AS path regular expression.

- . Matches any single character.
- * Matches 0 or more occurrences of pattern.
- + Matches 1 or more occurrences of pattern.
- ? Match 0 or 1 occurrences of pattern.
- ^ Matches the beginning of the line.
- \$ Matches the end of the line.
- Character _ has special meanings in AS path regular expression. It matches to space and comma , and AS set delimiter { and } and AS confederation delimiter (and). And it also matches to the beginning of the line and the end of the line. So _ can be used for AS value boundaries match. show ip bgp regexp _7675_ matches to all of BGP routes which as AS number include 7675.

9.7.2 Display BGP Routes by AS Path

To show BGP routes which has specific AS path information show ip bgp command can be used.

show ip bgp regexp line

Command

This commands display BGP routes that matches AS path regular expression line.

9.7.3 AS Path Access List

AS path access list is user defined AS path.

ip as-path access-list word {permit|deny} line

Command

This command defines a new AS path access list.

no ip as-path access-list word no ip as-path access-list word {permit|deny} line Command Command

9.7.4 Using AS Path in Route Map

match as-path wordRoute Mapset as-path prepend as-pathRoute Map

9.7.5 Private AS Numbers

9.8 BGP Communities Attribute

BGP communities attribute is widely used for implementing policy routing. Network operators can manipulate BGP communities attribute based on their network policy. BGP communities attribute is defined in RFC1997 - BGP Communities Attribute and RFC1998 - An Application of the BGP Community Attribute in Multi-home Routing. It is an optional transitive attribute, therefore local policy can travel through different autonomous system.

Communities attribute is a set of communities values. Each communities value is 4 octet long. The following format is used to define communities value.

AS:VAL This format represents 4 octet communities value. AS is high order 2 octet in digit format. VAL is low order 2 octet in digit format. This format is useful to define AS oriented policy value. For example, 7675:80 can be used when AS 7675 wants to pass local policy value 80 to neighboring peer.

internet internet represents well-known communities value 0.

no-export

no-export represents well-known communities value NO_EXPORT (0xFFFFF01). All routes carry this value must not be advertised to outside a BGP confederation boundary. If neighboring BGP peer is part of BGP confederation, the peer is considered as inside a BGP confederation boundary, so the route will be announced to the peer.

no-advertise

no-advertise represents well-known communities value NO_ADVERTISE (0xFFFFFF02). All routes carry this value must not be advertise to other BGP peers.

local-AS represents well-known communities value NO_EXPORT_SUBCONFED (0xFFFFFF03). All routes carry this value must not be advertised to external BGP peers. Even if the neighboring router is part of confederation, it is considered as external BGP peer, so the route will not be announced to the peer.

When BGP communities attribute is received, duplicated communities value in the communities attribute is ignored and each communities values are sorted in numerical order.

9.8.1 BGP Community Lists

BGP community list is a user defined BGP communities attribute list. BGP community list can be used for matching or manipulating BGP communities attribute in updates.

There are two types of community list. One is standard community list and another is expanded community list. Standard community list defines communities attribute. Expanded community list defines communities attribute string with regular expression. Standard community list is compiled into binary format when user define it. Standard community list will be directly compared to BGP communities attribute in BGP updates. Therefore the comparison is faster than expanded community list.

ip community-list standard name {permit|deny} community

Command

This command defines a new standard community list. community is communities value. The community is compiled into community structure. We can define multiple community list under same name. In that case match will happen user defined order. Once the community list matches to communities attribute in BGP updates it return permit or deny by the community list definition. When there is no matched entry, deny will be returned. When community is empty it matches to any routes.

ip community-list expanded name {permit|deny} line

Command

This command defines a new expanded community list. *line* is a string expression of communities attribute. *line* can include regular expression to match communities attribute in BGP updates.

no ip community-list name

Command

no ip community-list standard name no ip community-list expanded name Command Command

These commands delete community lists specified by *name*. All of community lists shares a single name space. So community lists can be removed simpley specifying community lists name.

show ip community-list show ip community-list name

Command

Command

This command display current community list information. When *name* is specified the specified community list's information is shown.

```
# show ip community-list
Named Community standard list CLIST
    permit 7675:80 7675:100 no-export
    deny internet
Named Community expanded list EXPAND
    permit :
```

show ip community-list CLIST
Named Community standard list CLIST
 permit 7675:80 7675:100 no-export
 deny internet

9.8.2 Numbered BGP Community Lists

When number is used for BGP community list name, the number has special meanings. Community list number in the range from 1 and 99 is standard community list. Community list number in the range from 100 to 199 is expanded community list. These community lists are called as numbered community lists. On the other hand normal community lists is called as named community lists.

ip community-list <1-99> {permit|deny} community

Command

This command defines a new community list. <1-99> is standard community list number. Community list name within this range defines standard community list. When *community* is empty it matches to any routes.

ip community-list <100-199> {permit|deny} community

Command

This command defines a new community list. <100-199> is expanded community list number. Community list name within this range defines expanded community list.

ip community-list name {permit|deny} community

Command

When community list type is not specifed, the community list type is automatically detected. If *community* can be compiled into communities attribute, the community list is defined as a standard community list. Otherwise it is defined as an expanded community list. This feature is left for backward compability. Use of this feature is not recommended.

9.8.3 BGP Community in Route Map

In Route Map (see Chapter 12 [Route Map], page 73), we can match or set BGP communities attribute. Using this feature network operator can implement their network policy based on BGP communities attribute.

Following commands can be used in Route Map.

match community word exact-match

Route Map

Route Map

This command perform match to BGP updates using community list word. When the one of BGP communities value match to the one of communities value in community list, it is match. When exact-match keyword is specified, match happen only when BGP updates have completely same communities value specified in the community list.

set community none

Route Map

set community community

Route Map

set community community additive

Route Map

This command manipulate communities value in BGP updates. When none is specified as communities value, it removes entire communities attribute from BGP updates. When community is not none, specified communities value is set to BGP updates. If BGP updates already has BGP communities value, the existing BGP communities value is replaced with specified community value. When additive keyword is specified, community is appended to the existing communities value.

set comm-list word delete

Route Map

This command remove communities value from BGP communities attribute. The word is community list name. When BGP route's communities value matches to the community list word, the communities value is removed. When all of communities value is removed eventually, the BGP update's communities attribute is completely removed.

9.8.4 Display BGP Routes by Community

To show BGP routes which has specific BGP communities attribute, show ip bgp command can be used. The *community* value and community list can be used for show ip bgp command.

```
show ip bgp community
show ip bgp community community
show ip bgp community community exact-match
```

Command Command

show ip bgp community displays BGP routes which has communities attribute. When community is specified, BGP routes that matches community value is displayed. For this command, internet keyword can't be used for community value. When exactmatch is specified, it display only routes that have an exact match.

```
show ip bgp community-list word
show ip bgp community-list word exact-match
```

Command Command

This commands display BGP routes that matches community list word. When exactmatch is specified, display only routes that have an exact match.

9.8.5 Using BGP Communities Attribute

Following configuration is the most typical usage of BGP communities attribute. AS 7675 provides upstream Internet connection to AS 100. When following configuration exists in AS 7675, AS 100 networks operator can set local preference in AS 7675 network by setting BGP communities attribute to the updates.

```
router bgp 7675
 neighbor 192.168.0.1 remote-as 100
neighbor 192.168.0.1 route-map RMAP in
ip community-list 70 permit 7675:70
ip community-list 70 deny
ip community-list 80 permit 7675:80
ip community-list 80 deny
ip community-list 90 permit 7675:90
ip community-list 90 deny
route-map RMAP permit 10
match community 70
 set local-preference 70
route-map RMAP permit 20
match community 80
 set local-preference 80
route-map RMAP permit 30
 match community 90
 set local-preference 90
```

Following configuration announce 10.0.0.0/8 from AS 100 to AS 7675. The route has communities value 7675:80 so when above configuration exists in AS 7675, announced route's local preference will be set to value 80.

```
router bgp 100
network 10.0.0.0/8
neighbor 192.168.0.2 remote-as 7675
neighbor 192.168.0.2 route-map RMAP out
```

```
!
ip prefix-list PLIST permit 10.0.0.0/8
!
route-map RMAP permit 10
match ip address prefix-list PLIST
set community 7675:80
```

Following configuration is an example of BGP route filtering using communities attribute. This configuration only permit BGP routes which has BGP communities value 0:80 or 0:90. Network operator can put special internal communities value at BGP border router, then limit the BGP routes announcement into the internal network.

```
router bgp 7675
  neighbor 192.168.0.1 remote-as 100
  neighbor 192.168.0.1 route-map RMAP in
!
ip community-list 1 permit 0:80 0:90
!
route-map RMAP permit in
  match community 1
```

Following exmaple filter BGP routes which has communities value 1:1. When there is no match community-list returns deny. To avoid filtering all of routes, we need to define permit any at last.

```
router bgp 7675
neighbor 192.168.0.1 remote-as 100
neighbor 192.168.0.1 route-map RMAP in
!
ip community-list standard FILTER deny 1:1
ip community-list standard FILTER permit
!
route-map RMAP permit 10
match community FILTER
```

Communities value keyword internet has special meanings in standard community lists. In below example internet act as match any. It matches all of BGP routes even if the route does not have communities attribute at all. So community list INTERNET is same as above example's FILTER.

```
ip community-list standard INTERNET deny 1:1
ip community-list standard INTERNET permit internet
```

Following configuration is an example of communities value deletion. With this configuration communities value 100:1 and 100:2 is removed from BGP updates. For communities value deletion, only permit community-list is used. deny community-list is ignored.

```
router bgp 7675
neighbor 192.168.0.1 remote-as 100
neighbor 192.168.0.1 route-map RMAP in
!
ip community-list standard DEL permit 100:1 100:2
!
route-map RMAP permit 10
set comm-list DEL delete
```

9.9 BGP Extended Communities Attribute

BGP extended communities attribute is introduced with MPLS VPN/BGP technology. MPLS VPN/BGP expands capability of network infrastructure to provide VPN functionality. At the same time it requires a new framework for policy routing. With BGP Extended Communities Attribute we can use Route Target or Site of Origin for implementing network policy for MPLS VPN/BGP.

BGP Extended Communities Attribute is similar to BGP Communities Attribute. It is an optional transitive attribute. BGP Extended Communities Attribute can carry multiple Extended Community value. Each Extended Community value is eight octet length.

BGP Extended Communities Attribute provides an extended range compared with BGP Communities Attribute. Adding to that there is a type field in each value to provides community space structure.

There are two format to define Extended Community value. One is AS based format the other is IP address based format.

AS:VAL This is a format to define AS based Extended Community value. AS part is 2 octets Global Administrator subfield in Extended Community value. VAL part is 4 octets Local Administrator subfield. 7675:100 represents AS 7675 policy value 100.

IP-Address:VAL

This is a format to define IP address based Extended Community value. IP-Address part is 4 octets Global Administrator subfield. VAL part is 2 octets Local Administrator subfield. 10.0.0.1:100 represents

9.9.1 BGP Extended Community Lists

Expanded Community Lists is a user defined BGP Expanded Community Lists.

ip extcommunity-list standard name {permit|deny} extcommunity Command

This command defines a new standard extcommunity-list. extcommunity is extended communities value. The extcommunity is compiled into extended community structure. We can define multiple extcommunity-list under same name. In that case match will happen user defined order. Once the extcommunity-list matches to extended communities attribute in BGP updates it return permit or deny based upon the extcommunity-list definition. When there is no matched entry, deny will be returned. When extcommunity is empty it matches to any routes.

ip extcommunity-list expanded name {permit|deny} line Command This command defines a new expanded extcommunity-list. line is a string expression of extended communities attribute. line can include regular expression to match

of extended communities attribute. *line* can include regular expression to match extended communities attribute in BGP updates.

no ip extcommunity-list name no ip extcommunity-list standard name Command Command

no ip extcommunity-list expanded name

Command

These commands delete extended community lists specified by name. All of extended community lists shares a single name space. So extended community lists can be removed simpley specifying the name.

show ip extcommunity-list show ip extcommunity-list name Command

Command

This command display current extcommunity-list information. When name is specified the community list's information is shown.

show ip extcommunity-list

9.11 Capability Negotiation

When adding IPv6 routing information exchange feature to BGP. There were some proposals. IETF IDR working group finally take a proposal called Multiprotocol Extension for BGP. The specification is described in RFC2283. The protocol does not define new protocols. It defines new attributes to existing BGP. When it is used exchanging IPv6 routing information it is called BGP-4+. When it is used for exchanging multicast routing information it is called MBGP.

bgpd supports Multiprotocol Extension for BGP. So if remote peer supports the protocol, bgpd can exchange IPv6 and/or multicast routing information.

Traditional BGP does not have the feature to detect remote peer's capability whether it can handle other than IPv4 unicast routes. This is a big problem using Multiprotocol Extension for BGP to operational network. draft-ietf-idr-bgp4-cap-neg-04.txt is proposing a feature called Capability Negotiation. bgpd use this Capability Negotiation to detect remote peer's capabilities. If the peer is only configured as IPv4 unicast neighbor, bgpd does not send these Capability Negotiation packets.

By default, Quagga will bring up peering with minimal common capability for the both sides. For example, local router has unicast and multicast capabilitie and remote router has unicast capability. In this case, the local router will establish the connection with unicast only capability. When there are no common capabilities, Quagga sends Unsupported Capability error and then resets the connection.

If you want to completely match capabilities with remote peer. Please use strict-capability-match command.

neighbor peer strict-capability-match no neighbor peer strict-capability-match

BGP

BGP

Strictly compares remote capabilities and local capabilities. If capabilities are different, send Unsupported Capability error then reset connection.

You may want to disable sending Capability Negotiation OPEN message optional parameter to the peer when remote peer does not implement Capability Negotiation. Please use dont-capability-negotiate command to disable the feature.

neighbor peer dont-capability-negotiate no neighbor peer dont-capability-negotiate

BGP

BGP

Suppress sending Capability Negotiation as OPEN message optional parameter to the peer. This command only affects the peer is configured other than IPv4 unicast configuration.

When remote peer does not have capability negotiation feature, remote peer will not send any capabilities at all. In that case, bgp configures the peer with configured capabilities.

You may prefer locally configured capabilities more than the negotiated capabilities even though remote peer sends capabilities. If the peer is configured by override-capability, bgpd ignores received capabilities then override negotiated capabilities with configured values.

neighbor peer override-capability no neighbor peer override-capability

BGP BGP

Override the result of Capability Negotiation with local configuration. Ignore remote peer's capability value.

9.12 Route Reflector

bgp cluster-id a.b.c.d

BGP

neighbor peer route-reflector-client no neighbor peer route-reflector-client

BGP BGP

9.13 Route Server

At an Internet Exchange point, many ISPs are connected to each other by external BGP peering. Normally these external BGP connection are done by full mesh method. As with internal BGP full mesh formation, this method has a scaling problem.

This scaling problem is well known. Route Server is a method to resolve the problem. Each ISP's BGP router only peers to Route Server. Route Server serves as BGP information exchange to other BGP routers. By applying this method, numbers of BGP connections is reduced from $O(n^*(n-1)/2)$ to O(n).

Unlike normal BGP router, Route Server must have several routing tables for managing different routing policies for each BGP speaker. We call the routing tables as different views. bgpd can work as normal BGP router or Route Server or both at the same time.

9.13.1 Multiple instance

To enable multiple view function of bgpd, you must turn on multiple instance feature beforehand.

bgp multiple-instance

Command

Enable BGP multiple instance feature. After this feature is enabled, you can make multiple BGP instances or multiple BGP views.

no bgp multiple-instance

Command

Disable BGP multiple instance feature. You can not disable this feature when BGP multiple instances or views exist.

When you want to make configuration more Cisco like one,

bgp config-type cisco

Command

Cisco compatible BGP configuration output.

When bgp config-type cisco is specified,

"no synchronization" is displayed. "no auto-summary" is desplayed.

"network" and "aggregate-address" argument is displayed as "A.B.C.D M.M.M.M"

Quagga: network 10.0.0.0/8 Cisco: network 10.0.0.0

Quagga: aggregate-address 192.168.0.0/24 Cisco: aggregate-address 192.168.0.0 255.255.255.0

Community attribute handling is also different. If there is no configuration is specified community attribute and extended community attribute are sent to neighbor. When user manually disable the feature community attribute is not sent to the neighbor. In case of "bgp config-type cisco" is specified, community attribute is not sent to the neighbor by default. To send community attribute user has to specify "neighbor A.B.C.D send-community" command.

! router bgp 1 neighbor 10.0.0.1 remote-as 1 no neighbor 10.0.0.1 send-community !

! router bgp 1 neighbor 10.0.0.1 remote-as 1 neighbor 10.0.0.1 send-community!

bgp config-type zebra

Command

Quagga style BGP configuration. This is default.

9.13.2 BGP instance and view

BGP instance is a normal BGP process. The result of route selection goes to the kernel routing table. You can setup different AS at the same time when BGP multiple instance feature is enabled.

router bgp as-number

Command

Make a new BGP instance. You can use arbitrary word for the name.

```
bgp multiple-instance
!
router bgp 1
neighbor 10.0.0.1 remote-as 2
neighbor 10.0.0.2 remote-as 3
!
router bgp 2
neighbor 10.0.0.3 remote-as 4
neighbor 10.0.0.4 remote-as 5
```

BGP view is almost same as normal BGP process. The result of route selection does not go to the kernel routing table. BGP view is only for exchanging BGP routing information.

router bgp as-number view name

Command

Make a new BGP view. You can use arbitrary word for the *name*. This view's route selection result does not go to the kernel routing table.

With this command, you can setup Route Server like below.

```
bgp multiple-instance
!
router bgp 1 view 1
neighbor 10.0.0.1 remote-as 2
neighbor 10.0.0.2 remote-as 3
!
router bgp 2 view 2
neighbor 10.0.0.3 remote-as 4
neighbor 10.0.0.4 remote-as 5
```

9.13.3 Routing policy

You can set different routing policy for a peer. For example, you can set different filter for a peer.

```
bgp multiple-instance
!
router bgp 1 view 1
neighbor 10.0.0.1 remote-as 2
neighbor 10.0.0.1 distribute-list 1 in
!
router bgp 1 view 2
neighbor 10.0.0.1 remote-as 2
neighbor 10.0.0.1 distribute-list 2 in
```

This means BGP update from a peer 10.0.0.1 goes to both BGP view 1 and view 2. When the update is inserted into view 1, distribute-list 1 is applied. On the other hand, when the update is inserted into view 2, distribute-list 2 is applied.

9.13.4 Viewing the view

To display routing table of BGP view, you must specify view name.

show ip bgp view name

Command

Display routing table of BGP view name.

9.14 How to set up a 6-Bone connection

```
zebra configuration
============
! Actually there is no need to configure zebra
bgpd configuration
! This means that routes go through zebra and into the kernel.

9.15 Dump BGP packets and table

```
dump bgp all path
dump bgp all path interval
Dump all BGP packet and events to path file.
```

Command Command

Chapter 9: BGP 65

dump bgp updates path dump bgp updates path interval Dump BGP updates to path file. Command Command

dump bgp routes path dump bgp routes path

Command Command

Dump whole BGP routing table to path. This is heavy process.

Guagga Quagga

10 VTY shell

vtysh is integrated shell of Quagga software.

To use vtysh please specify —enable-vtysh to configure script. To use PAM for authentication use —with-libpam option to configure script.

vtysh only searches /usr/local/etc path for vtysh.conf which is the vtysh configuration file. Vtysh does not search current directory for configuration file because the file includes user authentication settings.

Currently, vtysh.conf has only two commands.

username username nopassword

Command

With this set, user foo does not need password authentication for user vtysh. With PAM vtysh uses PAM authentication mechanism.

If vtysh is compiled without PAM authentication, every user can use vtysh without authentication. vtysh requires read/write permission to the various daemons vty sockets, this can be accomplished through use of unix groups and the –enable-vty-group configure option.

write-conf daemon Command

Instruct daemons to write out their config files when 'write file' is issued.

write-conf integrated

Command

Write out integrated Quagga.conf file when 'write file' is issued.

This command controls the behaviour of vtysh when it is told to write out the configuration. If write-conf integrated is set, the daemon will write out a Quagga.conf with all daemons' commands integrated into it. If write-conf daemon is set, vtysh will instruct each daemon to write out their config files.

Vtysh per default behaves as if write-conf daemon is set. Note that both may be set at same time if one wishes to have both Quagga.conf and daemon specific files written out. Further, note that the daemons are hard-coded to first look for the integrated Quagga.conf file before looking for their own file.

We recommend you do not mix the use of the two types of files. Further, it is better not to use the integrated Quagga.conf file, as any syntax error in it can lead to /all/ of your daemons being unable to start up. Per daemon files are more robust as impact of errors in configuration are limited to the daemon in whose file the error is made.

11 Filtering

Quagga provides many very flexible filtering features. Filtering is used for both input and output of the routing information. Once filtering is defined, it can be applied in any direction.

11.0.1 IP Access List

```
access-list name permit ipv4-network access-list name deny ipv4-network
```

Command Command

Basic filtering is done by access-list as shown in the following example.

```
access-list filter deny 10.0.0.0/9 access-list filter permit 10.0.0.0/8
```

11.0.2 IP Prefix List

ip prefix-list provides the most powerful prefix based filtering mechanism. In addition to access-list functionality, ip prefix-list has prefix length range specification and sequential number specification. You can add or delete prefix based filters to arbitrary points of prefix-list using sequential number specification.

If no ip prefix-list is specified, it acts as permit. If ip prefix-list is defined, and no match is found, default deny is applied.

```
ip prefix-list name (permit|deny) prefix [le len] [ge len] Command ip prefix-list name seq number (permit|deny) prefix [le len] [ge Command len]
```

You can create ip prefix-list using above commands.

seq number can be set either automatically or manually. In the case that sequential numbers are set manually, the user may pick any number less than 4294967295. In the case that sequential number are set automatically, the sequential number will increase by a unit of five (5) per list. If a list with no specified sequential number is created after a list with a specified sequential number, the list will automatically pick the next multiple of five (5) as the list number. For example, if a list with number 2 already exists and a new list with no specified number is created, the next list will be numbered 5. If lists 2 and 7 already exist and a new list with no specified number is created, the new list will be numbered 10.

le le command specifies prefix length. The prefix list will be applied if the prefix length is less than or equal to the le prefix length.

ge ge command specifies prefix length. The prefix list will be applied if the prefix length is greater than or equal to the ge prefix length.

Less than or equal to prefix numbers and greater than or equal to prefix numbers can be used together. The order of the le and ge commands does not matter.

If a prefix list with a different sequential number but with the exact same rules as a previous list is created, an error will result. However, in the case that the sequential number and the rules are exactly similar, no error will result.

If a list with the same sequential number as a previous list is created, the new list will overwrite the old list.

Matching of IP Prefix is performed from the smaller sequential number to the larger. The matching will stop once any rule has been applied.

In the case of no le or ge command,

Version 0.85: the matching rule will apply to all prefix lengths that matched the prefix list.

Version 0.86 or later: In the case of no le or ge command, the prefix length must match exactly the length specified in the prefix list.

no ip prefix-list name

Command

11.0.2.1 ip prefix-list description

ip prefix-list name description desc

Command

Descriptions may be added to prefix lists. This command adds a description to the prefix list.

no ip prefix-list name description [desc]

Command

Deletes the description from a prefix list. It is possible to use the command without the full description.

11.0.2.2 ip prefix-list sequential number control

ip prefix-list sequence-number

Command

With this command, the IP prefix list sequential number is displayed. This is the default behavior.

no ip prefix-list sequence-number

Command

With this command, the IP prefix list sequential number is not displayed.

11.0.2.3 Showing ip prefix-list

show ip prefix-list

Command

Display all IP prefix lists.

show ip prefix-list name

Command

Show IP prefix list can be used with a prefix list name.

show ip prefix-list name seq num

Command

Show IP prefix list can be used with a prefix list name and sequential number.

show ip prefix-list name a.b.c.d/m

Command

If the command longer is used, all prefix lists with prefix lengths equal to or longer than the specified length will be displayed. If the command first match is used, the first prefix length match will be displayed.

show ip prefix-list name a.b.c.d/m longer

Command

show ip prefix-list name a.b.c.d/m first-match

Command

show ip prefix-list summary

Command

show ip prefix-list summary name

Command

show ip prefix-list detail

Command

show ip prefix-list detail name

Command

11.0.2.4 Clear counter of ip prefix-list

clear ip prefix-list

Command

Clears the counters of all IP prefix lists. Clear IP Prefix List can be used with a specified name and prefix.

clear ip prefix-list name

Command

clear ip prefix-list name a.b.c.d/m

Command

12 Route Map

Route map is a very useful function in zebra. There is a match and set statement permitted in a route map.

route-map test permit 10
match ip address 10
set local-preference 200

This means that if a route matches ip access-list number 10 it's local-preference value is set to 200.

12.0.1 Route Map Command

route-map route-map-name permit priority

Command

12.0.2 Route Map Match Command

match ip address access_list

Route-map Command

Matches the specified access_list

match ip next-hop ipv4_addr

Route-map Command

Matches the specified *ipv4_addr*.

match aspath as_path

Route-map Command

Matches the specified as_path.

match metric metric

Route-map Command

Matches the specified metric.

match community community_list

Route-map Command

12.0.3 Route Map Set Command

Matches the specified community_list

set ip next-hop ipv4_address

Route-map Command

Set the BGP nexthop address.

set local-preference local-pref

Route-map Command

Set the BGP local preference.

set weight weight

Route-map Command

Set the route's weight.

set metric metric

Route-map Command

Set the BGP attribute MED.

set as-path prepend as-path

Set the BGP AS path to prepend.

Route-map Command

set community community

Set the BGP community attribute.

Route-map Command

set ipv6 next-hop global ipv6_address

Set the BGP-4+ global IPv6 next hop address. Route-map Command

set ipv6 next-hop local ipv6_address

Set the BGP-4+ link local IPv6 nexthop address.

Route-map Command

13 IPv6 Support

Quagga fully supports IPv6 routing. As described so far, Quagga supports RIPng, OSPFv3 and BGP-4+. You can give IPv6 addresses to an interface and configure static IPv6 routing information. Quagga IPv6 also provides automatic address configuration via a feature called address auto configuration. To do it, the router must send router advertisement messages to the all nodes that exist on the network.

13.1 Router Advertisement

no ipv6 nd supress-ra

Interface Command

Send router advertisment messages.

ipv6 nd supress-ra

Interface Command

Don't send router advertisment messages.

ipv6 nd prefix ipv6prefix [valid-lifetime] [preferred-lifetime] [off-link] [no-autconfig]

Interface Command

Configuring the IPv6 prefix to include in router advertisements. Several prefix specific optional parameters and flags may follow:

• valid-lifetime - the length of time in seconds during what the prefix is valid for the purpose of on-link determination. Value *infinite* represents infinity (i.e. a value of all one bits (0xffffffff)).

Range: <0-4294967295> Default: 2592000

• preferred-lifetime - the length of time in seconds during what addresses generated from the prefix remain preferred. Value *infinite* represents infinity.

Range: <0-4294967295> Default: 604800

• off-link - indicates that advertisement makes no statement about on-link or off-link properties of the prefix.

Default: not set, i.e. this prefix can be used for on-link determination.

• no-autoconfig - indicates to hosts on the local link that the specified prefix cannot be used for IPv6 autoconfiguration.

Default: not set, i.e. prefix can be used for autoconfiguration.

ipv6 nd ra-interval SECONDS no ipv6 nd ra-interval

Interface Command
Interface Command

The maximum time allowed between sending unsolicited multicast router advertisements from the interface, in seconds. Must be no less than 3 seconds.

Default: 600

ipv6 nd ra-lifetime SECONDS no ipv6 nd ra-lifetime

Interface Command
Interface Command

The value to be placed in the Router Lifetime field of router advertisements sent from the interface, in seconds. Indicates the usefulness of the router as a default router

on this interface. Setting the value to zero indicates that the router should not be considered a default router on this interface. Must be either zero or between value specified with *ipv6 nd ra-interval* (or default) and 9000 seconds.

Default: 1800

ipv6 nd reachable-time MILLISECONDS no ipv6 nd reachable-time

Interface Command Interface Command

The value to be placed in the Reachable Time field in the Router Advertisement messages sent by the router, in milliseconds. The configured time enables the router to detect unavailable neighbors. The value zero means unspecified (by this router). Must be no greater than 3,600,000 milliseconds (1 hour).

Default: 0

ipv6 nd managed-config-flag no ipv6 nd managed-config-flag

Interface Command Interface Command

Set/unset flag in IPv6 router advertisements which indicates to hosts that they should use managed (stateful) protocol for addresses autoconfiguration in addition to any addresses autoconfigured using stateless address autoconfiguration.

Default: not set

ipv6 nd other-config-flag no ipv6 nd other-config-flag

Interface Command Interface Command

Set/unset flag in IPv6 router advertisements which indicates to hosts that they should use administered (stateful) protocol to obtain autoconfiguration information other than addresses.

Default: not set

interface eth0

no ipv6 nd supress-ra

ipv6 nd prefix 2001:0DB8:5009::/64

For more information see RFC2462 (IPv6 Stateless Address Autoconfiguration) and RFC2461 (Neighbor Discovery for IP Version 6 (IPv6)).

14 Kernel Interface

There are several different methods for reading kernel routing table information, updating kernel routing tables, and for looking up interfaces.

'ioctl' The 'ioctl' method is a very traditional way for reading or writing kernel information. 'ioctl' can be used for looking up interfaces and for modifying interface addresses, flags, mtu settings and other types of information. Also, 'ioctl' can insert and delete kernel routing table entries. It will soon be available on almost any platform which zebra supports, but it is a little bit ugly thus far, so if a better method is supported by the kernel, zebra will use that.

'sysctl' can lookup kernel information using MIB (Management Information Base) syntax. Normally, it only provides a way of getting information from the kernel. So one would usually want to change kernel information using another method such as 'ioctl'.

'proc filesystem'

'proc filesystem' provides an easy way of getting kernel information.

'routing socket'

'netlink' On recent Linux kernels (2.0.x and 2.2.x), there is a kernel/user communication support called netlink. It makes asynchronous communication between kernel and Quagga possible, similar to a routing socket on BSD systems.

Before you use this feature, be sure to select (in kernel configuration) the kernel/netlink support option 'Kernel/User network link driver' and 'Routing messages'.

Today, the /dev/route special device file is obsolete. Netlink communication is done by reading/writing over netlink socket.

After the kernel configuration, please reconfigure and rebuild Quagga. You can use netlink as a dynamic routing update channel between Quagga and the kernel.

15 SNMP Support

SNMP (Simple Network Managing Protocol) is a widely implemented feature for collecting network information from router and/or host. Quagga itself does not support SNMP agent (server daemon) functionality but is able to connect to a SNMP agent using the SMUX protocol (RFC1227) and make the routing protocol MIBs available through it.

15.1 Getting and installing an SNMP agent

There are several SNMP agent which support SMUX. We recommend to use the latest version of net-snmp which was formerly known as ucd-snmp. It is free and open software and available at http://www.net-snmp.org/ and as binary package for most Linux distributions. net-snmp has to be compiled with --with-mib-modules=smux to be able to accept connections from Quagga.

15.2 SMUX configuration

To enable SMUX protocol support, Quagga must have been build with the --enable-snmp option.

A separate connection has then to be established between between the SNMP agent (snmpd) and each of the Quagga daemons. This connections each use different OID numbers and passwords. Be aware that this OID number is not the one that is used in queries by clients, it is solely used for the intercommunication of the daemons.

In the following example the ospfd daemon will be connected to the snmpd daemon using the password "quagga_ospfd". For testing it is recommending to take exactly the below snmpd.conf as wrong access restrictions can be hard to debug.

```
/etc/snmp/snmpd.conf:
#
# example access restrictions setup
#
com2sec readonly default public
group MyROGroup v1 readonly
view all included .1 80
access MyROGroup "" any noauth exact all none none
#
# the following line is relevant for Quagga
#
smuxpeer .1.3.6.1.4.1.3317.1.2.5 quagga_ospfd
/etc/quagga/ospf:
! ... the rest of ospfd.conf has been omitted for clarity ...
smux peer .1.3.6.1.4.1.3317.1.2.5 quagga_ospfd
!
```

After restarting snmpd and quagga, a successful connection can be verified in the syslog and by querying the SNMP daemon:

```
snmpd[12300]: [smux_accept] accepted fd 12 from 127.0.0.1:36255
snmpd[12300]: accepted smux peer: \
oid GNOME-PRODUCT-ZEBRA-MIB::ospfd, quagga-0.96.5

# snmpwalk -c public -v1 localhost .1.3.6.1.2.1.14.1.1
OSPF-MIB::ospfRouterId.0 = IpAddress: 192.168.42.109
```

Be warned that the current version (5.1.1) of the Net-SNMP daemon writes a line for every SNMP connect to the syslog which can lead to enormous log file sizes. If that is a problem you should consider to patch snmpd and comment out the troublesome snmp_log() line in the function netsnmp_agent_check_packet() in agent/snmp_agent.c.

15.3 MIB and command reference

no smux peer oid password

The following OID numbers are used for the interprocess communication of snmpd and the Quagga daemons. Sadly, SNMP has not been implemented in all daemons yet.

```
(OIDs below .iso.org.dod.internet.private.enterprises)

zebra .1.3.6.1.4.1.3317.1.2.1 .gnome.gnomeProducts.zebra.zserv

bgpd .1.3.6.1.4.1.3317.1.2.2 .gnome.gnomeProducts.zebra.bgpd

ripd .1.3.6.1.4.1.3317.1.2.3 .gnome.gnomeProducts.zebra.ripd

ospfd .1.3.6.1.4.1.3317.1.2.5 .gnome.gnomeProducts.zebra.ospfd

The following OID numbers are used for querying the SNMP daemon by a client:

zebra .1,3,6,1,2,1,4,24 .iso.org.dot.internet.mgmt.mib-2.ip.ipForward

ospfd .1.3.6.1.2.1.14 .iso.org.dot.internet.mgmt.mib-2.ospf

bgpd .1.3.6.1.2.1.15 .iso.org.dot.internet.mgmt.mib-2.bgp

ripd .1.3.6.1.2.1.23 .iso.org.dot.internet.mgmt.mib-2.rip2
```

The following syntax is understood by the Quagga daemons for configuring SNMP:

smux peer oid
no smux peer oidCommand
Commandsmux peer oid passwordCommand

Command

Appendix A Zebra Protocol

Zebra Protocol is a protocol which is used between protocol daemon and zebra. Each protocol daemon sends selected routes to zebra daemon. Then zebra manages which route is installed into the forwarding table.

Zebra Protocol is a TCP-based protocol. Below is common header of Zebra Protocol.

```
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2 3 4 5 6 7 8 9 0 1 1 2
```

Length is total packet length including this header length. So minimum length is three. Command is Zebra Protocol command.

```

Appendix B Packet Binary Dump Format

Quagga can dump routing protocol packet into file with a binary format (see Section 9.15 [Dump BGP packets and table], page 64).

It seems to be better that we share the MRT's header format for backward compatibility with MRT's dump logs. We should also define the binary format excluding the header, because we must support both IP v4 and v6 addresses as socket addresses and / or routing entries.

In the last meeting, we discussed to have a version field in the header. But Masaki told us that we can define new 'type' value rather than having a 'version' field, and it seems to be better because we don't need to change header format.

Here is the common header format. This is same as that of MRT.

If 'type' is PROTOCOL_BGP4MP, 'subtype' is BGP4MP_STATE_CHANGE, and Address Family == IP (version 4)

| 0 1 | 2 | 3 | | |
|--|-------------------------|------------|--|--|

BGP4 Attribute must not contain MP_UNREACH_NLRI. If BGP Attribute has MP_REACH_NLRI field, it must has zero length NLRI, e.g., MP_REACH_NLRI has only Address Family, SAFI and next-hop values.

If 'type' is PROTOCOL_BGP4MP and 'subtype' is BGP4MP_SNAPSHOT,

The file specified in "File Name" contains all routing entries, which are in the format of "subtype == BGP4MP_ENTRY".

Constants:

```
/* type value */
#define MSG_PROTOCOL_BGP4MP 16
/* subtype value */
#define BGP4MP_STATE_CHANGE 0
#define BGP4MP_MESSAGE 1
#define BGP4MP_ENTRY 2
#define BGP4MP_SNAPSHOT 3
```
